Preface

The present report describes the main characteristics of the Labour Force Surveys in the then 25 Member States of the European Union, the four Candidate Countries and three EFTA countries in 2005.

All but one of the Countries provide Eurostat with LFS micro-data for publication. Due to legal considerations Turkey has not been able until 2006 to deliver any micro-data. The aim of this report is to provide users with the means to accurately interpret the LFS results by providing information regarding the technical features of the Labour Force Surveys carried out in these countries.

In 2005 Germany became the last Member State to implement the continuous quarterly survey.

The LFS measures the labour status and other characteristics of the population in an average week in each quarter, by spreading the sample uniformly over all the weeks of the quarter.

The main characteristics of the national practices are presented herein. The information is organised on the same lines as the methodological data for 2004 in *The European Union labour force survey: main characteristics of the national surveys 2004*. This will enable users to evaluate the degree of comparability achieved. Tables 1 to 3 at the end of the report provide summary information for some of the characteristics described in the report, while table 4 provides information on how the reference weeks are distributed over the year.

For more detailed information on the common practices and definitions of the European Labour Force Survey see *The European Union Labour Force Survey, Methods and Definitions, 2001*.

The information necessary for preparing this publication was mainly collected in 2006. Eurostat wishes to thank the experts responsible for the national labour force surveys in the Member States, Candidate and EFTA countries for their help in compiling the information presented in this publication.

Characteristics of national surveys in 2005

**BELGIUM (BE)**

**General**

The survey started in 1983 as an annual survey, but has been continuous since January 1999 providing quarterly and yearly results.

The survey covers the entire country. Only private households are included where at least one person is younger than 75 years old.

Participation in the survey is compulsory.

The household is the simple or collective unit comprising either one person living alone or two or more persons, whether or not of the same family, who usually occupy the same dwelling and live there together.

**Sampling plan**

The planned quarterly sample size is 11,960 households, which represents an average survey rate of about 0.3%. Every week 920 households should be interviewed.

The survey is based on a 2 level stratified sampling plan.

The survey base is the National Register of Persons, which is derived from communal population registers.

The entire national territory is divided into provinces (NUTS-2) forming 11 strata. The allocation is proportional to the square root of the number of households in each province. This increases the sampling rate of the least-populated strata.

Within each stratum, a two-stage sampling is carried out. The primary units comprise parts of the communes called ‘statistical sections’ (6,192 in the whole country, with 704 households in average and covering 5 km² in average). Their probability of selection is proportional to the number of households in them, with replacement of any ‘small’ section (at most 27 households) by another section of the same municipality; the ‘small’ sections only represent 0.15% of the total number of households.

The secondary sampling unit is the household.

Within each primary unit, 23 households (both in the Flemish and Walloon region) or 26 (in the Brussels region) are drawn at random using a method which ensures that the entire register of the primary unit in question is covered.

The overall survey rate (secondary units) is identical for all municipalities in each stratum.
Weighting procedure

Extrapolation to the population, including adjustments for non-response, is done at the level of individuals, using a posteriori stratification by province (NUTS-2), sex and age (5-year age groups). In each of the post-strata thus obtained, a weight is calculated whose numerator is the population at the middle of the quarter according to the National Register of Persons and whose denominator the number of usable responses.

Data collection

The detailed information (related to individuals aged 15 years and over) is collected by means of face-to-face interviews in the 3 weeks following the reference week. In households of retired persons, interviews can be conducted by telephone.

The field staff comprises 300-350 persons.

In 2005, 22.6% of the interviews of persons aged 15-74 years were carried out by authorised third parties. In terms of initially drawn households, the response rate is 79.3%. Refusals were 10% of the total non-response.

A second interview takes place 3 months after (except for people aged 65 years and over) by mail or by telephone, with a shorter version of the questionnaire which aims only to measure the ILO labour situation (employed, unemployed and inactive).

BULGARIA (BG)

General

The survey started in 1993, providing quarterly results from 2000 based on a single reference week in the last month of the quarter. In 2003 the survey was redesigned as a continuous Labour Force Survey, providing quarterly results.

The survey covers the whole country. Only private households are included. Persons, living in student hostels or in workers’ hostels are treated as private households.

All households, covered in the sample, are surveyed within three months with the reference period evenly spread throughout 12 weeks of the quarter.

Participation in the survey is voluntary.

The resident population includes all persons usually residing in Bulgaria, including persons temporarily abroad (less than one year). The survey covers all the members of the selected households including conscripts and people absent from home due to: business trip, seasonal or temporal work, tourism, temporary (less than 6 months) stay in hospitals or other health institutions for medical cure and other.

A household is defined as a group of two or more people living together in a house or a part of a house and having common budget. The person stating that they do not belong to any household and that they live on their own budget is considered as a single person household.
Sampling plan

The Labour force survey is based on two-stage stratified cluster sample. Clusters at the first stage are the enumeration districts and at the second stage - households. In the first stage 2 250 enumeration districts are selected with probability proportional to the population in the districts. In the second stage eight households are sampled with systematic random sample from each PSU.

The sample consists of three independent sub-samples of enumeration districts for each month of a quarter. The households from each of these sub-samples are evenly spread through the 4 weeks in a month. Each month, 6 000 households in 750 enumeration districts are observed, e.g. 1 500 households per week.

The sample is stratified by districts (28 administrative districts at NUTS-3 level), crossing with urban/rural area.

The base for the LFS sample is provided by 2001 Population Census. The enumeration districts and households in the sample have been selected from the list roll of enumeration districts and households prepared during the March 2001 Population Census.

The sample unit is the household. In total 18 000 households are sampled each quarter, corresponding to an overall sampling rate of 0.6%.

A 2-(2)-2-rotation pattern is used. According to the rotation scheme (applied since March 1996) half of the households (4 in each enumeration district) stay in the sample for two consecutive quarters. Respondents are interviewed in two consecutive quarters, then temporarily are removed for the next two quarters and enter again for the following two quarters afterwards being definitely removed from the survey.

Weighting procedure

The current population estimates as of 31 December of the preceding year are used for weighting the results. These data do not exclude institutional population, although it is not covered by the survey. Data obtained by the survey are post-stratified by 28 districts, urban/rural areas, sex and 4 age groups. All persons in each of these 448 strata have the same weight. The weight is calculated by dividing the population in each stratum by the number of interviewed persons in the same stratum.

Data collection

The data are collected with face-to-face interviews, using paper questionnaires. All persons in the household aged 15 years and over are interviewed.

The interviews are carried out by about 445 interviewers (incl. those working part-time on LFS) who are mainly the staff of the regional offices of NSI.

In 2005 42% of the interviews of persons aged 15-74 years were by proxy.

The average response rate in 2005 was 83.3%. Refusals were 23% of the total non-response.
**CZECH REPUBLIC (CZ)**

**General**

The survey has been conducted since December 1992 as a continuous quarterly survey, going over from seasonal quarters to calendar quarters by the end of 1997.

The survey covers the whole country. Only private households are surveyed.

Participation in the survey is voluntary.

The target population comprises all persons living usually in the households of the selected dwellings. The temporarily absent persons (for not more than 1 year) and domestic servants are included. People in student or worker’s homes are included if satisfying this rule. Lodgers are considered as independent budget keeping households. People living abroad are excluded. Conscripts are surveyed for demographic background only.

**Sampling Plan**

The sampling plan is stratified two-stage probability sample of dwelling units.

The strata consist of 77 districts with Prague considered one district.

The primary sampling units are census areas that are sampled (by randomised systematic sampling) with probability proportional to size, i.e. the number of dwellings per census area, using the Register of Census Areas as a sampling frame.

In the second stage, dwelling units are selected from the initial sample by simple random sampling.

The initial sample of PSUs is 5 650 census areas, while the approximate final sample size is 25 000 dwelling units, constituting an overall sampling fraction of 0.6%.

Each quarterly sample consists of five panels interviewed for five quarters consecutively until rotated out of the sample.

**Weighting Procedure**

The weights are based on the post-stratification to 12 age groups, sex and the 77 districts. The demographic figures for individual quarters 2005 were forecasted from the definitive demographic data for end-of-year 2004 with assuming a migration and natural increase.

**Data Collection**

Data are collected in first visits with face-to-face interviews, with repeated interviews are partly made by telephone (23%). In the 2nd quarter, when ad hoc module is surveyed, almost all interviews are face-to-face. All interviews were conducted with the aid of electronic questionnaires with few exceptions.
All persons aged 15 years and older and living in the sampled dwellings are interviewed.

The number of field workers was 113 in 2005.

In 2005, 48.1% of the interviews of persons aged 15-74 years were carried out by proxy. The response rate was 80.2%. Refusals were 72% of the total non-response.

**DENMARK (DK)**

**General**

The survey started in 1984 as an annual survey, but has been organised as a continuous survey, providing quarterly results since 1994.

The entire country is covered, apart from Greenland and the Faroe Islands.

The survey covers persons living in either private or collective households.

There is no specific national legislation making it compulsory to provide information for the survey, and participation is therefore voluntary.

The resident population comprises persons with domicile in Denmark (excluding Greenland and the Faeroe Islands) according to the Central Population Register.

**Sampling plan**

The quarterly sample size is 16,665 persons, which represents an average survey rate of 0.4%.

The sampling unit is the individual.

A stratified sample design is used. The sampling frame is the Central Population Register and the Unemployment Register.

The quarterly sample size of the people aged 15-66 is 15,600. Persons aged 16-66 years that were registered as unemployed in a specific quarter prior to the survey quarter are selected with a higher probability than their relative proportion of the total population. Thus, Stratum 1) is drawn from the Unemployment Register whereas other 15-66 year olds (Stratum 2)) are drawn from the Population Register. Additional 1,065 individuals aged 67-74 years are drawn from the Population Register (Stratum 3)).

Respondents are surveyed 3 times. First time in the initial quarter, then the following quarter and for the third time a year apart from the initial quarter. One-third of the sample is renewed each quarter.

**Weighting procedure**

The three strata are weighted separately:
I. Initial weights:

For Strata 1) and 2) the following register-based information is used to derive initial non-response weights:

Stratum 1) Age (16-29, 30-54, 55-66), Education (“None”, “Vocational training, trainees or apprentices” and "Higher education"), Gross income (<202 500 DKK, 202 500+ DKK)

Stratum 2) Age (15-29, 30-54, 55-66), Gross income (<135 000 DKK, 135 000-269 999 DKK, 270 000+ DKK), Group of industry (“Production”, "Other private", "Public" and "No information”).

II. Weighting by sex and (mainly) 5 years age groups:

After this step weighting is performed by using a combination of sex and mainly 5 years age groups for the 3 sampling strata separately, based on quarterly updated data from the Population Register.

Stratum 1) sex and age (16-24, 25-29, 30-34, 35-39, 40-44, 45-49, 50-54, 55-59, 60-66);

Stratum 2) sex and age (15-19, 20-24, 25-29, 30-34, 35-39, 40-44, 45-49, 50-54, 55-59, 60-66);

Stratum 3) sex

III. Region

No regional-adjustment is made, as Denmark is considered a homogeneous region at NUTS-2 level.

Data collection

The Danish LFS uses a mix of modes. The main part of the interviews (92% in 2005) is conducted via telephone interviewing (CATI). Persons who could not be reached by telephone receive a mailed questionnaire. Demographic information (e.g. sex, year of birth, marital status, nationality) and level of education, training and the year of completion are variables obtained from the statistical registers based on administrative sources (The Population Register and The Educational Statistical System).

The field staff comprises approximately 40 part-time interviewers and 10 supervisors.

Less than 3% of the interviews (of persons 15-74 years) were carried out by authorised third parties. However, from 2002 special proxy household interviewing has been implemented, so selected data on household composition as well as main status and labour status for the other household members are collected via proxy interviewing in the third (and last) wave with the current respondents.
The response rate was 63.4% in 2005. The exact percentage of refusals is difficult to calculate, because it is impossible to know if a questionnaire sent by post but not returned represents a refusal or some other kind of non-response.

**GERMANY (DE)**

**General**

The Labour Force Sample Survey is carried out as part of the annual micro-census, which is based on the ‘micro-census law’. The micro-census has been carried out since 1957 in the old West-Germany, but since 1991 in the new Bundesländer and East-Berlin. In general the micro-census is compulsory. Additionally, the questionnaire includes optional parts of the LFS and other special national programmes. Starting in 2005 the survey was organised as a continuous survey covering all weeks of the year, providing quarterly results. At the same time the questionnaire was revised, especially questions relating to employment in the reference week.

The survey covers private and collective households, except for military quarters. A private household comprises either a person living alone or two or more persons, irrespective of their relationship. The members of a private household are characterised by the same dwelling and common housekeeping. National service personnel and students are included in their parents' households.

The resident population (statistical population) includes all inhabitants with their main place of residence in the territory of the Federal Republic. Foreign armed forces and members of the diplomatic corps and their families are excluded.

The reference week is the week before the interview.

**Sampling plan**

There are three sources used for the sampling plan. The census data from 1987 is the survey base for the ‘old’ federal States. The central population register of the German Democratic Republic gives data for the ‘new’ federal States. Both statistics are annually updated by the register of new dwellings. The sample is an area sample covering all areas of Germany. Sampling units are the sampling districts comprising of 9 dwellings on the average. Statistical units are the households in the sampling districts.

All buildings are attributed to one of three strata, depending on the number of dwellings they comprise. The first stratum contains a number of buildings which are close to one another (but not necessarily contiguous) and comprising fewer than five dwellings. In this stratum, each sampling district comprises about 12 dwellings. The second stratum comprises buildings with between five and 10 dwellings. Each of these buildings constitutes a sampling district. The buildings in the third stratum comprise 11 dwellings or more. In this stratum, the ‘sampling district’ is a subdivision of the building, the target size being 6 dwellings. An additional stratum covers the population living in collective households. It is divided into sampling units with a target size of 15 persons.
All persons in a selected sampling district are interviewed.

The sampling districts are stratified by region and size of the buildings. The stratification by size of the buildings is based on the size classes used to work out the sampling units. The sampling rate is the same in each stratum. Within each stratum, an effect similar to stratification is obtained by systematic sampling in a list classified by geographical entity.

The regions comprise an average of 350,000 inhabitants. The list of sampling districts is sorted within each stratum by sub-region, Kreis (administrative district), the size class of the commune, commune and number of the sample district. This list is divided into groups of 100 consecutive sampling districts. A sample of 1% is drawn at random for the micro-census in each of these groups and allocated to each month of the year. The average quarterly sample in 2005 comprises about 165,000 respondents.

A rotation system is composed of four waves. Each address remains in the sample for four years and 25% of the sample is replaced each year. No one is interviewed more than once a year.

**Weighting procedure**

A two-stage adjustment procedure is used.

(a) If possible, limited data are collected for households which fail to respond. These data can include: number of persons of the household, nationality (German/foreign) and for households comprising only one person: age (under or over 60 years) and sex. From this data, the weightings of respondent households are increased to take account of non-responses in the region.

(b) The sample, weighted to take account of non-response, is stratified *a posteriori* by region, sex, age (<15, 15-44, 45+) and nationality (German/foreign) and is extrapolated to the population (adjusted of military personnel).

**Data collection**

The field staff of the 15 statistical offices of the Länder comprises about 1,500 interviewers. All information should be collected by face-to-face interviews. In some cases (approximately 15%), the interviewers are not able to contact members of the household. In that case, a questionnaire is sent to the household by post and a hotline is offered. One person (18 years or older) is allowed to answer instead of the rest of the household. All interviews are carried out with the help of portable computers (CAPI).

Proxy interviews of persons 15-74 years were 26.6% in 2005.

The response rate in 2005 was 95.6%.
**ESTONIA (EE)**

**General**

The Estonian Labour Force Survey started in 1997 as an annual survey. Since 2000 the Estonian LFS has been organised as a continuous quarterly survey.

The survey covers the whole country. Both private and collective households are surveyed.

Participation in the survey is voluntary.

The target population comprises all persons aged 15-74 years with permanent residence in Estonia, i.e. the people who have lived or intend to live in Estonia for more than one year.

The household is made up either of persons living alone or of two or more persons who share a household budget and usually occupy the same dwelling.

**Sampling Plan**

The sample size per quarter is approximately 2 500 households, with a sampling rate of approximately 0.5% of the working age population.

The sampling frame is based on the Population Register, comprising all resident persons aged 15-74 years.

Until 2005 the sampling design was a stratified systematic two-phase sampling of individuals, whose households are included in the sample in the second phase with probability inverse to the number of persons age 15-74 in the household. Since 1st quarter of 2005 the design was changed to a stratified systematic one-phase sampling of individuals. In the new sampling design gradually implemented from 2005, the individuals are systematically sampled within each stratum and their households included in the sample.

Change to the new design is done according to the 2-(2)-2 rotation plan as each new panel is selected. The 15 counties of Estonia and Tallinn are divided into four strata according to the population size (I – Tallinn, II – four bigger counties, III – ten smaller counties, IV – Hiiu County) and different inclusion probabilities are used in the strata, the highest being for Hiiu County.

Every sampled household is interviewed for four quarters according to the rotation pattern 2-(2)-2.

**Weighting Procedure**

The weights are formed in a sequence of steps. A weight resulting from the previous step is multiplied by the correction factor calculated at the current step. The correction factors are scaled in such a way that their sample average is unity at each step. As a result, the final weight is a product of the initial weight and correction factors.
As stratified sampling is used on the first step of sample formation, first the initial weight that is inversely proportional to the inclusion probability in each stratum is calculated.

For non-response adjustment the non-response correction factors are computed. The response homogeneous groups of reasonably uniform size of sampled households are formed on the basis of the place of residence of the household according to the non-response rate in the region. Within each group the correction factor is inversely proportional to the overall response rate in the region.

In the next step the weights are calibrated so that they produce exact population numbers in certain subgroups known from demographic data (including institutional population). For working-age persons the subgroups by sex, age (5-years age groups), the place of residence (urban/rural area, 15 counties (NUTS 4 level) and the capital city) and Estonians/non-Estonians are considered. For this purpose the linear consistent weighting method is applied.

For nonworking age persons the non-calibrated household’s weights are calibrated by sex and 5-years age groups.

Data Collection

In the first three quarters of 2005, 90% of interviews were face to face interviews (paper / pencil) and 10% computer assisted personal interviews (CAPI). Since 4th quarter of 2005 the main data collection method is CAPI. All interviews are conducted by 60 interviewers of the Data Collection Department of Statistics Estonia. The interviewing is normally done during the week immediately following the reference week but never later than five weeks following the reference week. About 15% of the interviews of persons 15-74 years old were by proxy.

The response rate in 2005 was 74.9%. Refusals were 31% of the total non-response.

IRELAND (IE)

General

The Quarterly National Household Survey started in September 1997, replacing the annual April Labour Force Survey (1983-1997). The survey is a continuous one, providing quarterly results. The quarters refer to the seasonal quarters, i.e. the winter quarter (1st quarter) refers to December of the previous year, January and February, and so on. In 2005 the first reference week started on Monday 29 November 2004.

The population comprises persons who usually reside on Irish territory.

All the regions are covered.

Only private households are included.
The private household is made up either of persons living alone or of two or more persons, whether or not of the same family, usually occupying the same dwelling and sharing a joint budget.

There is no specific legislation making it compulsory to provide information for the survey. Participation is therefore voluntary.

**Sampling plan**

A two-stage sample design is used. This comprises a first stage sample of 2,600 blocks (or small areas) selected at county level to proportionately represent eight strata reflecting population density. Each block was selected to contain, on average, 75 dwellings and the sample of blocks is fixed for a period of about five years. In the second stage of sampling, each block is split into rotation groups each containing 15 households. Each quarter one rotation group from within a given block is surveyed to give a total quarterly sample of 39,000 households with 3,000 households interviewed every week of the quarter.

The primary sampling units are stratified as follows:

1. County Boroughs
2. Suburbs of County Boroughs
3. Environs of County Boroughs
4. Towns 10,000 +
5. Towns 5,001 - 10,000
6. Towns 1,000 - 5,000
7. Mixed Urban/Rural Areas
8. Rural Areas

The base for the sampling frame is the 2002 Census of population.

Households are asked to take part in the survey for five consecutive quarters and are then replaced by other households in the same block. Thus, one fifth of the households in the survey are replaced each quarter and the QNHS sample involves an overlap of 80% between consecutive quarters and 20% between the same quarters in consecutive years.

**Weighting procedure**

The expansion factor is to population totals.

The survey results are weighted to agree with population estimates broken down by age (5 year age groups), sex and region (NUTS-3 regions). The estimates are calculated as follows:
1. The previous quarter’s population estimate or census of population at regional level is used as the base population.

2. A quarter of this population is aged on by 1 year.

3. Births for the relevant period are added to each region – source = registered births.

4. Deaths for relevant period are subtracted from each region – source = registered deaths.

5. Net migration (inflows from other regions minus outflows to other regions plus inflows from abroad minus outflows to abroad) is added to each region – main source = Quarterly National Household Survey (QNHS – formerly annual Labour Force Survey).

The result is the new population estimate at regional level.

Data collection

Interviews are carried out on a face-to-face basis with the help of portable computers (CAPI). All the information is obtained by interview.

The field staff comprises approx. 140 interviewers plus 30 back-up interviewers.

43% of the interviews were carried out by authorised third parties.

The response rate 2005 was 90.1%.

GREECE (EL)

General

The survey started as an annual survey covering all weeks of the second quarter in 1983. In 1998 it was redesigned as a continuous survey providing quarterly results.

It covers only private households. Participation in the survey is compulsory.

The resident population comprises persons who usually reside on Greek territory and who spend most days and nights there.

Sampling plan

The sample size is about 36 000 households, which represents a survey rate of 0.85%.

The sampling frame is based on the census. The sampling design is a two stage probability sampling of dwellings. Each area unit (primary unit - one or more building blocks) of the stratum has a probability of being selected proportional to its size (number of households in the last population census of the year 2001). In second stage the sample of dwelling units is selected from each primary unit with systematic
selection with equal probabilities. If more than one household lives in the selected dwelling, all of them are interviewed.

In each Department (NUTS-3), the stratification of primary units was conducted by allocating the Municipalities and Communes according to the degree of urbanization (urban, semi-urban, and rural regions). Except for the two major city agglomerations (Athens and Thessaloniki) the produced strata according to the degree of urbanization are:

Urban Stratum: Agglomerations and Municipalities with 10.000 inhabitants or more
Semi-urban Stratum: Municipalities and Communes with 2.000 to 9.999 inhabitants
Rural Stratum: Communes up to 1.999 inhabitants

The Greater Athens Area was divided into 31 strata of about equal size (equal number of households) on the basis of the lists of city blocks of the municipalities that constitute it and taking into consideration socio-economic criteria. Similarly, the Greater Thessaloniki Area was divided into 9 equally sized strata. The two Major City Agglomerations account for 40% of total population and for even larger percentages in certain socio-economic variables.

A rotation system comprising six waves is used. Each sampling unit is kept in the sample for six consecutive quarters.

Weighting procedure
The survey weights are adjusted every quarter so that the estimated (from the survey) total population coincides with the estimated (from the projection of the 2001 census results) population by region (NUTS-2), age groups, and sex (for the members of private households).

Data collection
All the information is collected by means of face-to-face interviews (printed questionnaires).

The field staff comprises 600 interviewers.

43.6% of the interviews of persons 15-74 years old were carried out by proxy.

No information is available for the non-response rate in 2005.

SPAIN (ES)

General
The Spanish Labour Force Survey was launched for the first time in 1964, referencing to some quarters each year in until 1968. In 1969-74 it was biannual, but quarterly from 1975. In 1999 the survey was redesigned as a continuous survey
providing quarterly results. Since 2005 the survey provides quarterly results for core variables, but annual results for structural variables.

Since 1996 the survey is compulsory as it was included in the yearly statistical programme.

The population residing in private households is covered, including servants; persons living in collective households and persons who are temporarily absent are sampled via the relatives living in private household. Foreign nationals are included in the resident population if they have lived or intend to live in Spain for more than one year.

The household concept used is that of the ‘dwelling household’ (all people living in the dwelling are interviewed).

**Sampling plan**

The sample size is approximately 65 000 households, which represents an average survey rate of 0.4% of the population living in the country.

The sampling is a two-stage sampling procedure with stratification of the primary units. First stage units are geographical areas in which all the country is split. These areas are stratified within each province, using the population size of the municipality. Within each stratum, the areas are sub-stratified according to the socio-economic characteristics of the population.

Second stage units are private households (dwelling units).

The sample is made up of six rotation groups. Household once selected remain in the sample for six consecutive quarters before being replaced. In any quarter, households of one wave are receiving the first interview; households of another wave are receiving the second interview, and so on.

Each quarter, the household sample in one sixth of the primary unit sampled, is replaced by a new sample. Thus, there is an 83% potential overlap in the samples for each consecutive quarter.

The sample size of primary units is 3 588 and, the average sample size of the secondary units in each area is in general 18, but 22 in the big metropolitan areas.

Units are selected in such a way to obtain self-weighted samples within each stratum. The first stage units are selected with proportional probability to the size and second stage units are selected with equal probability.

**Weighting procedure**

The design uses Ratio Estimator and the auxiliary variable is the Population Projection at stratum level.

Every quarter, population projections by age group (0–15 years and 16 years +) and NUTS-2 region are made. Projections by age and region are distributed by stratum in
proportion to the population of each stratum. In each stratum, age group and region, the weighting is determined by the ratio of the projection to the sample size.

The sample is then calibrated in order to adjust to the population distribution. The auxiliary information used is the population by sex, age (0-4, 5-9, 10-15, 16-19, 20-24, ..., 65+), nationality (nationals-non nationals) and NUTS-2.

A linear weighting method is used, in which each member of the household has the same weight.

**Data collection**

All the information is collected by interview. The first interviews are personal interviews. Interviews in the second and subsequent waves are carried out by telephone, except when the family wants a personal interview or there is no telephone. All interviews are done with the help of portable computers.

The field staff comprises 318 interviewers per quarter.

52.9% of the interviews of persons 16-74 years old were carried out by authorised third parties.

The average response rate in 2005 was 80.4%. Refusals were 46% of the total non-response.

**FRANCE (FR)**

**General**

The French Labour Force Survey was launched in 1950, organised in 1982 as an annual survey. Redesigned in 2003, the survey is a continuous survey providing quarterly results.

The survey covers private households in metropolitan France.

It includes part of the population living in collective households, persons who have family ties with private households.

Participation in the survey is compulsory.

The resident population comprises persons living on French metropolitan territory.

The household concept used is that of the ‘dwelling household’: a household means all persons living in the same dwelling. It may consist of a single person, or of two families living in the same dwelling.

**Sampling plan**

All 15 years old or more individuals in the household are surveyed.
All weeks of the year are reference weeks. Data collection is continuous. The quarterly sample is distributed among its 13 weeks.

The results are quarterly. Each quarter consists in 13 reference weeks. The sample is representative of the French population each quarter.

The sample of the new quarterly survey is made with geographical delimited areas (aires). From a theoretical point of view, the sampling method consists in a stratification of Metropolitan France in 189 strata (21 French regions x 9 types of urban units), and a first stage sampling of areas in each stratum (with different probabilities, average sampling rate = 1/600). Areas contain about 20 dwellings, and among them only dwellings which are main residences are surveyed.

The base used for the sample is the Population Census of 1999. New dwellings (constructed between the date of the Census and the date of the survey) in the areas are listed by the surveyor at the time of the survey. If the area contains less than 10 new dwellings, all of them are surveyed; if the area contains between 10 and 40 new dwellings, 10 of them are surveyed (srs); if the area contains more than 40 new dwellings, a quarter of them are surveyed (srs).

The sample unit is the dwelling: in each sampled area, every private household living in its main residence is surveyed.

The sample rate is about 1/600 for a given quarter. In the preceding annual survey, the sample rate was 1/300 for a given year.

Each quarter, about 54 000 dwellings are sampled. Among them, about 35 000 include at least one respondent, i.e. 75 000 persons 15 years old or more.

The stratification is crossing two criteria: French region (NUTS-2) and type of urban unit (21 regions x 9 types of urban unit).

Each area is surveyed six quarters consecutively. Each quarter, the sample contains 6 sub-samples: 1/6 of the sample is surveyed for the first time, 1/6 is surveyed for the second time, 1/6 is surveyed for the 6th (and last) time.

**Weighting procedure**

The expansion factor is the population totals (15 years old or more) less the estimated number of persons living in communities.

1. a correction for non-response is made, using several criteria: size of urban unity, number of rooms in the housing, type of housing (individual house, building…), and number of new dwellings.

2. an adjustment with the population pyramid (at the middle of the quarter) by five-year age groups and gender is made for each sub-sample.
**Data collection**

The collection method is a face-to-face interview for the first and the last interrogations and a telephone interview for intermediate interrogations (2nd to 5th). The first interview lasts on average 15 minutes, the following ones 7 to 9 minutes.

About 590 interviewers work for the French LFS per quarter.

About 32% of the interviews were carried out by authorised third parties.

The average response rate in 2005 was 80.9%. Refusals were 22% of the total non-response.

**ITALY (IT)**

**General**

The Italian Labour Force Survey was launched as a quarterly survey in 1959. Since the beginning of 2004 the survey is a continuous one, covering all weeks of the year. Survey results are produced and disseminated on quarterly bases. Professional status for every analysis unit in the sample is referred to a specific week (reference week), usually the one preceding the interview.

Participation in the survey is compulsory. All the regions are covered.

The resident population is that recorded in the population registers of Italian communes. Only private households are included. The private household is made up either of persons living alone or of two or more persons, whether or not of the same family, usually occupying the same dwelling.

**Sampling plan**

In 2005 the quarterly sample size was 76,872 households, giving an average survey rate of 0.3%.

The sample frame is a stratification of the primary units (municipalities) in each NUTS-2 (Region) based on the population of the municipality. The ultimate sampling units are the households and are drawn randomly from municipal registers.

Stratification of the municipalities in each NUTS-2 region is based on the population of the communes.

The households are rotated according to a 2-(2)-2 rotation plan. Households are interviewed during two consecutive quarters. After a two-quarter interval, they are again interviewed twice in the corresponding two quarters of the following year. As a result, each household is included in four waves of the survey.

**Weighting procedure**

The estimates of the survey are obtained through a calibration estimator.
The procedure for working out the grossing weights is based on the solution of a minimisation problem under constraints, which requires the equalisation of the sampling estimates of certain auxiliary variables (in particular gender and age) with their respective total obtained from demographic estimates based on different sources.

The grossing weight is determined as follows:

- Firstly, the base weighting factor is obtained as the inverse ratio of the probability of inclusion of any sample household;
- Then, the correction factor for total non-response is worked out as the reciprocal of the response ratio for each strata;
- Then, the correction factor that assures that the sample replies the same structure as the population, with regard to the distribution by sex and 5-year age groups at NUT 2 area and by sex and five age groups of different width at NUT 3 area, is finally determined.

This procedure is applied iteratively to ensure that all members of a given household have the same final weight.

Weighting factors are calculated on quarterly basis, whereas annual estimates are calculated as averages of quarterly estimates.

**Data collection**

The information is collected through computer assisted personal (CAPI) or telephone (CATI) interviews carried out by professional interviewers under ISTAT direct control.

40% of the interviews of persons 15-74 years in 2005 were by authorised third party.

Personal interviews, carried out by 310 professional interviewers under ISTAT direct control, concern 1st wave interviews, all interviews made in particular periods such as summer or Christmas holidays, 2nd, 3rd and 4th waves interviews to households with no telephone. Telephone interviews, carried out in service by about 35 professional interviewers, concern all other cases.

The response rate in 2005 was on the average 90.6%. Refusals were approximately 38% of the total non-response.

**CYPRUS (CY)**

**General**

The Cypriot Labour Force Survey was launched in 1999 as an annual survey in the second quarter of the year. Starting with the second quarter 2004, the survey was redesigned as a continuous survey providing quarterly results.

The survey covers the areas of Cyprus controlled by the Government of the Republic of Cyprus. Only private households are covered.
Participation in the survey is compulsory.

The resident population comprises persons who usually reside in Cyprus or intend to stay in Cyprus for at least 12 months. It excludes Cypriot students studying abroad as well as foreign armed forces and foreigners who work in embassies or diplomatic missions.

The private household is made up either of persons living alone or of two or more persons, whether or not of the same family, usually occupying the same dwelling and sharing a joint budget.

**Sampling Plan**

The sampling plan is a stratified two-stage probability sampling of dwelling units.

The variables used for stratification are the Districts and the urban/rural areas within each district.

The selection of PSUs is based on probability proportional to size sampling. The size refers to the number of households enumerated in the Population Census of 2001. This list is updated by new enumerations every year.

The secondary sampling units (SSUs) are the dwelling units selected systematically from a list of all dwellings belonging to the selected PSUs. Refusals, non-contacts (households absent for more than one month) and households unable to respond are substituted by the next household on the sampling frame.

The sample size per year is approximately 4,500 dwelling units containing approximately 3,600 households, which represents an average sampling rate of 1.54%.

Each sample consists of 6 waves, 5 of which are carried over from the previous quarter. Each household is interviewed 6 times consecutively before being rotated out of the sample.

**Weighting Procedures**

The results are weighted *a posteriori* to the population in private households by sex and five-year age groups. No regional or urban/rural weighting is carried out.

**Data Collection**

Data in wave 1 are collected with face-to-face interviews by 4 field workers using CAPI. Data in subsequent waves (2-6) are collected with telephone interviews by 7 interviewers using CATI. The response rate before substitution in 2005 was 97.2%.

The number of proxy interviews of persons aged 15-74 years was 30% in 2005.
LATVIA (LV)

General
The Latvian Labour Force Survey started in November 1995, producing results in May and November each year. In 2002 the survey was redesigned as a continuous survey.

The survey covers the whole country. Only private households are surveyed.

Participation in the survey is voluntary.

The target population includes all the residents aged 15 to 74 years, with permanently residence in Latvia. Persons temporarily absent for one year or more are excluded.

A household is defined as a group of two or more persons living together in a house or a part of a house and share expenses for common living and eating. The person stating that he/she does not belong to any household and that he/she lives on his/her own budget is considered as a single person household.

Sampling Plan
The sampling plan is a two-stage stratified probability sample.

Two sampling frames are built for each sampling stage. At the first stage the list of Population census 2000 counting areas is used as sampling frame. All territory of Latvia was divided in small territories during the Population census 2000. The list contains information about the number of households in each counting area.

At the second stage sampling frame is built from The Population Register, statistical register of dwellings and statistical register of households.

The strata are defined by degree of urbanisation (Riga, six other largest towns, towns and rural areas).

The census counting areas constitute the primary sampling units with few exceptions. These are selected from each stratum using systematic sampling with probability proportional to size.

The final sampling units are 2574 households selected from the PSUs by a simple random sampling method. The overall sampling rate is approximately 0.3%.

Each household is interviewed three times with a six months interval.

Weighting Procedure
The initial weights are calculated according to the sample design, with all persons within the same PSU having equal design weights. The design weights are adjusted using the data of response level in each PSU. These weights were then adjusted on the basis of demographic data. The breakdown into groups was various for adjustment of quarterly and yearly weights. Demographic data were broken down by
degree of urbanisation (as in stratification), 14 age groups (0-14; 15-19; 20-24; 25-29; 30-34; 35-39; 40-44; 45-49; 50-54; 55-59; 60-64; 65-69; 70-74; over 75) and sex for adjustment of the quarterly weights. Demographic data were broken down by degree of urbanisation (as in stratification), NUTS-4 (33 units), 14 age groups and sex for adjustment of the yearly weights. All persons within the same household have equal initial weights, but the final weights tend to be diverse.

Data Collection

Data are collected throughout the year by 43 interviewers, with face-to-face interviews using paper questionnaires. 40% of the interviews of persons aged 15-74 years were collected from authorised third parties.

The average response rate in 2005 was 78.6%. Refusals were 35% of the total non-response.

**LITHUANIA (LT)**

General

The Lithuanian LFS started in April 1994 as a semi-annual survey with one reference week in the second and fourth quarter each. Since the third quarter 2002 the survey has been redesigned as a continuous survey.

The survey covers the whole country. Private households are surveyed.

Participation in the survey is voluntary.

The target population covers all residents 15 years and older living in private households, including those who are temporarily abroad for a period of less than a year. The population also includes foreign nationals who have been living in Lithuania at least a year. An additional sample is selected of children under the age of 15 years since 2002.

A private household comprises either persons living alone or two or more persons, whether they are of the same family or not, who usually occupy the same dwelling and share a common budget. Only the members of the selected private household (family) are interviewed.

Sampling Plan

The sampling plan is a one-stage simple random sample of 4 000 individuals aged 15 years and over, using the Population Register as a sampling frame.

The sample is constructed as follows: having selected a simple random sample of the fixed number of persons of the sampling frame, the members of their households are also added. Even in case turned out that according to the address sampled, a part of people or all of them were not included into the list of the sample, all persons actually living at the address are interviewed. A cluster sample of persons is thus obtained. All
the persons living at the address selected belong to the same cluster. The actual composition of the cluster is indicated by the interviewer when visiting the household.

Each household is surveyed for four quarters according to the rotation pattern 2-(1)-2.

**Weighting Procedure**

The weighting method for the Lithuanian LFS is based on the generalised calibration method introduced by Deville and Särndal in 1992. The initial household design weights are calculated taking into account the unequal selection probabilities of the households. These are then adjusted by the use of auxiliary information relating to population data on 10 NUTS-3 (counties) and the intersection of 13 age-groups, sex and urban/rural as well as data from the National Labour Exchange on the number of registered unemployed persons. Each member of the household receives the same weight as the household.

**Data Collection**

The first interview must be carried out face-to-face, while the subsequent interviews could be conducted according to the situation – by telephone or face-to-face. The interview normally takes place during the week immediately following the reference week but never later than the five weeks after the reference week. The interview is on the average about 20 minutes in the first interview and shorter in the subsequent interviews. If the target persons selected to the sample cannot be reached, a proxy may be used on certain conditions.

The field staff comprises 130 interviewers. The average response rate in 2005 was 87.6%. Refusals were 22% of the total non-response.

Approximately 43% of the interviews of persons aged 15-74 years were by proxy.

**LUXEMBOURG (LU)**

**General**

In 2003, a new survey design was launched for the Luxembourg LFS, which is characterized by continuous data collection by telephone interviews, replacing the annual survey in the spring from 1983.

The survey yields annual results as average of the whole year. The resident population comprises persons registered as residing in one of the communes.

There is no specific legislation making it compulsory to provide information for the survey. Participation is therefore voluntary.

The survey covers only private households.

The household is defined as persons living in the same household, other than subtenants and military personnel returning home at the weekend.
The demographic part of the questionnaire is submitted to all the household members. But only the 15-74 years old should be interviewed for the rest of questionnaire.

**Sampling plan**

Single stage stratified random sample

The Central Population Register (RGPP) is used to draw the sample. The strata result from the crossing of the canton and the household size class. There are 13 cantons in Luxembourg. The household size is divided into 4 classes: 1, 2, 3, and 4+. So, the product of the number of cantons (13) and the number of size classes (4) gives 52 strata.

The sampling unit are the households. All the individuals included in the aforementioned households are considered as targets of the survey.

A yearly sample is drawn and spread over 52 weeks. The households are randomly chosen by proportional allocation in each stratum, with the exception of under-populated strata, but with the constraint that its yearly minimum size be at least 48 households.

The sample size is 25 603 households, corresponding to a yearly sampling rate of 11.24%.

In 2005 6 401 households from previous year’s sample were incorporated in the sample.

**Weighting procedure**

The initial household weight is the inverse of the selection probability in each stratum. According to the general sharing weight method, all the individuals of the same household have the same weight.

1. A calibration is performed with CALMAR macro of INSEE-France for correcting the non-response. Among many variables like region (merger of cantons), household class size, age of reference person and citizenship of reference person, we try to find out, by logistic regression, by how much they account for the non-response phenomenon. These variables were selected: canton, size of household, and age of the reference person. Its purpose is to make the distribution of these variables in the sampling frame and in the set of respondents agree. Three “regions” are determined by grouping some cantons: North, Centre and South. The following classes are used for the age: 0-38, 39-49, 50-64, 65+. This calibration is implemented at the household level.

2. A final adjustment is carried out for getting more accurate estimates of the variables of interest. It consists in making the most recent distribution of sex * age class * citizenship in the population agree with the distribution of the same variables in the set of respondents. The following age classes are used: 0-14, 15-19, 20-24, 25-39, 40-54, 55-64, 65+. This calibration is implemented at the person level.
Data collection

The sample is divided into 52 reference weeks. Once a year, each selected household should be interviewed within 3 weeks from the reference week. All the interviews are carried out by telephone by four interviewers. One interview (covering the core variables as well as the ad hoc module variables) lasts in average 10 to 15 minutes per interviewed person.

In 2005, 52% of the interviews of persons 15-74 years old were carried out by authorised third parties.

The response rate is 33.0%. Refusals were 24% of the total non-response.

HUNGARY (HU)

General

The Hungarian Labour Force Survey started in 1992 as a quarterly survey. The quarterly sample is made up of three monthly sub-samples, producing monthly results with moving average of the last three month for some indicators since 2003. In 2003 the survey was redesigned so that each month three weeks are surveyed.

The survey covers the whole country. Only private households are surveyed.

Participation in the survey is voluntary.

The LFS provides labour market information on the non-institutional population aged 15-74 years. Included are household members temporarily absent and persons living abroad if they have common income/consumption with the surveyed household. The institutional and unsettled population is excluded, as well as conscripts. Demographic information is collected on all persons without age restrictions.

Sampling Plan

From 2003 the LFS sample is a mult-stage stratified sample of dwellings based on the 2001 Population and Housing Census.

The LFS sample is stratified by administrative units (i.e. the capital city and 19 counties) and by size categories of the localities. Total number of strata is 275, of which 171 are self-representing localities. The remaining 103 strata contain 513 non-self-representing sampled localities.

At national level, self-representative localities are those which have at least 3975 dwellings (i.e. approximately 5000 inhabitants), while all other localities are non-self-representative. The former are all included in the sample with certainty, while a stratified (sub-)sample is selected from the latter with probability proportional to size (PPS). In the case of non-self-representative localities, design strata are defined as cross-classes of four size categories and 19 administrative units (counties). In the case of non-self-representing localities, the primary sampling units (PSUs) are localities, and the secondary (and ultimate) sampling units are dwellings. By contrast,
the PSUs are dwellings in the case of self-representing localities, thus sampling has actually only one stage in this case.

The final sampling units are dwellings in each case. They are selected with systematic random sampling from lists of addresses belonging to the sampled localities. Prior to selection, the lists are properly sorted for the purpose of implicit stratification. As a result, the different parts of the localities (downtown areas, suburbs, etc.) will be properly represented. All households residing in the selected dwelling units are surveyed.

In the different strata of the LFS sample different sampling rates are used. The overall sampling fraction is 0.92%, yielding approximately 37 500 dwellings per quarter.

The sample has a simple rotation pattern. The households entering the sample provide information for six consecutive quarters, before being rotated out of the sample for good.

**Weighting Procedure**

At the first stage, design (or design based) weights are determined. For any stratum of the sample, the unique design weight is defined as the ratio of the total number of dwellings in the stratum to that in the sub-sample for that stratum. Some adjustments are also included at this stage.

At the second stage, calibrated weights are determined with the method of generalized raking. For each of the 20 geographical units (i.e. the capital city and the 19 counties), the calibration variables or controls are the following:

- totals for age-sex groups (2x10 totals),
- total number of households,
- total resident population in cities with at least 50 000 inhabitants.

The calibration is organized so that the members in any sample households have the same calibrated weight as the household.

Method of deriving controls: demographic components method combined with census-based proportions.

**Data Collection**

Data are collected throughout the year by some 491 field workers on the average using paper questionnaires. The first interview is face-to-face, while the subsequent interviews can be carried out over telephone. Interviews are done during the week immediately following the reference week.

The average response rate in 2005 was 87.5%. Refusals were 30% of the total non-response.
In 2005, 43% of the interviews of persons aged 15-74 years were collected from authorised third parties (proxy).

**MALTA (MT)**

**General**

The Maltese Labour Force Survey started in 2000 providing quarterly results from 2001. The survey was redesigned as a quarterly continuous survey in 2004. At the same time a new sampling frame was introduced.

The survey covers the whole country. Only private households are surveyed.

Participation in the survey is obligatory.

The survey covers private households, including people who are temporarily absent from the usual place of residence.

A household is defined as one or more persons who live together and share expenses. A person who is abroad during the reference week and who visits Malta on a regular basis, i.e. at least 2 times a year, is considered to be part of the household. Children or any other members who are living in another dwelling or institution are excluded.

**Sampling Plan**

The sampling plan is a one-stage systematic random sample of households from the Household Register - Water Services Corporation Database.

The sample is 2 500 households per quarter, with an effective sampling rate of 2%.

The sample consists of two panels. All the households that responded in the first wave are chosen for the second panel.

**Weighting Procedure**

A *posteriori* stratification at one level was performed by sex, age-group and district. This allows the tabulation of estimates on national and district levels. The totals are benchmarked to Census Population Totals.

For weighting procedures, NUTS-4 is used, and age groups consist of the ages between 0-15, 16-24, 25-34, 35-54, 55-64 and 65+ years.

**Data Collection**

Data are collected with face-to-face or telephone interviews by 60 interviewers. All persons in the household aged 15 years and over are interviewed. Each household is contacted via ordinary mail so that it is informed that family has been chosen to participate in the LFS. An interviewer who is assigned to a group of households carries the interview in either of two ways i.e. in person or by telephone. Households
which are selected for the second panel are contacted by telephone if a fixed line number is available. An interviewer is sent to those households who do not provide a telephone number or who do not have a telephone line or who do not want to be interviewed over the phone.

The average response rate in 2005 was 82.0%. Refusals were 15% of the total non-response.

In 2005, 48% of the interviews of persons aged 15-74 years were carried out by authorised third parties.

**NETHERLANDS (NL)**

**General**

The Dutch Labour Force Survey started in 1987 as an annual survey. In 2000 it was redesigned as a continuous quarterly survey.

The survey covers only private households.

The year is divided into quarters of 13 weeks: January to March, April to June, July to September and October to December. For each of these periods, the reference weeks are distributed uniformly over the 13 weeks.

There is no specific legislation making it compulsory to provide information for the survey. Participation is therefore voluntary.

The resident population comprises persons residing in the Netherlands.

The private household comprises either persons living alone or two or more persons, whether or not they are of the same family, who usually occupy the same dwelling and share a joint budget.

**Sampling plan**

The survey base is a list of all addresses drawn up by the postal services in combination with the Population Register. All institutions are eliminated from the sample. The file also contains information on the number of letterboxes at each address (mailing addresses), which are used as sampling units.

The sampling plan is a three stage stratified probability sample of addresses:

(a) primary sampling units: the municipalities;
(b) secondary sampling units: mailing addresses;
(c) tertiary sampling units: households.

Municipalities are selected with a probability proportional to their population. All municipalities with a population of more than 18 000 persons (of which there are about 200), are permanently represented in the survey.
Mailing addresses are selected systematically out of a mailing list sorted by postal code. At addresses with more than one letterbox, all letterboxes appear in the list. If a selected mailing address includes only one household, this household is questioned. If the address includes more than one household, only half of the households are questioned, with a maximum of three households. This makes it possible to increase the effectiveness of the survey. Sixty-six strata are defined using cross-classification based on 40 ‘Corop’ regions and 18 employment-exchange regions.

**Weighting procedure**

*A posteriori* stratification in two stages is applied, using independent demographic information. A linear weighting method in which each member of the household has the same weight is used. Four *a posteriori* stratifications are used:

- first, a detailed breakdown by age and sex,
- secondly, a broad breakdown by age and sex and a detailed breakdown by ethnic background,
- third, a broad breakdown by age and sex and marital status,
- finally, a detailed breakdown by region and a broad breakdown by age and sex.

The weights are benchmarked to the population totals without the institutional population.

**Data collection**

Interviews in the first wave are carried out face-to-face with the help of portable computers (CAPI). Interviews in the next four waves are carried out by telephone (CATI). The field staff comprises 220 CAPI and 95 CATI interviewers. The response rate in 2005 for the first wave was approximately 67%.

In 2005, 47% of the interviews of 15-74 years old persons were by proxy.

**AUSTRIA (AT)**

**General**

The Austrian Labour Force Survey started in 1995 as an annual survey in March. In 2004 the LFS in Austria was redesigned as a continuous, quarterly survey, covering all weeks of the year.

Only the population in private households is included in the European Union Labour Force Survey. Participation in the survey is compulsory.

The resident population comprises persons who have their main residence on Austrian territory during the reference week.
A private household is made up of all people actually living in a dwelling, independently registered in this dwelling or not.

**Sampling plan**

The survey base is the Central Population Register.

The sampling design is a stratified single random sample from the sampling frame, with each “Bundesland” forming a stratum.

The sampling unit is the dwelling with at least one person with main residence. All the people in the selected dwellings are surveyed.

The overall survey rate is 0.6%, which gives a sample of about 20 400 households.

A rotation system comprising 5 waves is used. Each dwelling is kept in the sample for five quarters and one-fifth of the sample is replaced each quarter.

**Weighting procedure**

The weights are calculated in two steps. In the first step for each record a basic weight which depends on the stratum is calculated. In the second step the weights are adjusted in such a manner that the resulting distribution is in accordance to the population within the federal provinces (Bundesländer). These figures correspond to the population with main residence at the beginning of each quarter minus persons in institutional households calculated by age-, sex- and nationality specific rates based on Census results 2001. The variables which are used for adjusting the data for each Bundesland are age and sex on the one side and nationality on the other side and furthermore household size. Age is grouped by 5 year age groups up to 85 years, except for children aged 0 - 2 and 3 - 4 years are weighted separately. Nationality groups are citizenship of Austria, Turkey and Ex-Yugoslavia, EU 14, others. Each member of the household has the same weight.

**Data collection**

Data is collected with face-to-face interviews using paper and pencil in the first wave (PAPI) and mostly computer assisted telephone interviewing (CATI) in the second to fifth wave.

The field staff comprises 140 PAPI and 80 CATI interviewers.

The average response rate in 2005 was 89.3%. Refusals were 1% of the total non-response.

Approximately 28% of the interviews with persons aged 15-74 years were carried out by authorised third parties (interviewing other adult members of the household).
POLAND (PL)

General

The Polish Labour Force Survey started in May 1992 as a quarterly survey, using data collection in one reference week per quarter. Since the 4th quarter 1999 the survey covered all weeks of the year.

The survey covers the whole country. Only non-institutional households are covered.

Participation in the survey is voluntary.

The target population covers all persons 15 years old and older with usual residence in Poland. Persons living in institutional households (army, hospital, prison etc.) and students living away from home for a total period exceeding two months are excluded from the survey. The same applies to persons living permanently or temporarily (for more than two months) in other countries.

The household is a group of relatives or other people living together and maintaining a joint unit. Persons not belonging to any household and living and managing the household alone are considered as single person households.

Sampling Plan

The sampling plan for the Polish LFS is a two-stage stratified probability sampling of dwelling units.

The sampling frame for both stages of the sample is based on the Domestic Territorial Division Register. The primary sampling units refer with few exceptions to census clusters in towns and enumeration districts in rural areas.

The primary sampling units are stratified by urban/rural division of voivodships (provinces), as well as division within voivodships depending on the size of the place, with rural areas included in the smallest ones. PSUs are sampled within strata with sampling probability proportional to the number of dwellings in a PSU.

In the second stage a total of 24 700 dwelling units per quarter are sampled from selected PSUs stratified by size of the municipality. This corresponds to 0.14% overall sampling rate.

The sample is divided into four sub-samples, subject to the rotation scheme 2-(2)-2.

Weighting Procedure

The weights are computed using a four-step procedure. First the initial design weights are calculated for dwelling units, i.e., the reciprocals of the selection probabilities for the final sampling units in each stratum. Secondly, the weighted response rates are calculated for sampling units stratified a posteriori by six place-of-residence categories. Thirdly, the initial weights are adjusted by the response rates. The final step consists of modifying the adjusted weights using the population estimates stratified a posteriori by the urban-rural division, sex and 12 age groups (15-17, 18-19, 20-24, 25-29, 30-34, 35-39, 40-44, 45-49, 50-54, 55-59, 60-64, 65+).
Data Collection

The data are collected by 808 field workers with face-to-face interviews using paper questionnaires. Repeated interviews are sometimes carried out by telephone.

The average response rate in 2005 was 78.8%. Refusals were 59% of the total non-response.

Approximately 42% of the interviews are by proxy.

PORTUGAL (PT)

General

The Portuguese LFS started in 1983 as a quarterly survey. Since 1998, the survey is a continuous one yielding quarterly results.

All the geographical territory of Portugal is covered, i.e. mainland, Madeira and the Azores.

Only private dwellings are covered, although the survey also covers part of the population living in collective dwellings and who represent a potential for the labour market, insofar as they have family links with the private dwellings (national servicemen or students).

Participation in the survey is compulsory (in accordance with Law No 6/89, Sistema Estatistico Nacional, of April 1989).

The resident population consists of individuals residing in a private dwelling during the reference week. Individuals who are absent for short periods of time and not occupying another dwelling permanently are also included.

A private dwelling is made up either of persons living alone or of 2 or more persons, whether or not they are of the same family, who usually occupy the same dwelling and share a common budget.

Sampling plan

The Portuguese LFS uses a two stage cluster sampling where the first stage consists of the construction of the 2001 Master Sample (MS2001).

The MS2001 is a stratified one-stage cluster sample constituted by private dwellings from the 2001 Census of Population and Housing. In each stratum (NUTS-3 or groups of NUTS-3 regions) the clusters were selected systematically with probability proportional to size (number of private dwellings of usual residence). The sampling frames for the MS2001 are the Census 2001 data and the BGRI-Geographic Information Referencing Base (geographical referencing system supported by digital topographic mapping and aerial photographs, containing the limits of administrative divisions and statistical divisions). The MS2001 consists of 1 408 ‘areas’ and it is representative at the level 3 of the NUTS.
After the selection of the geographical areas (primary units) of the MS2001 the LFS sample of private dwellings (secondary units) are selected sequentially in two systematic blocs.

All the persons living in the same dwelling are interviewed. Despite the survey being directed to the households, the dwellings are the sampling units.

A rotation system comprising six waves is used. Houses are kept in the sample for six consecutive quarters before being replaced by an identical number of houses in the same statistical section. One-sixth of the sample is replaced each quarter.

In each quarter 22 554 dwelling units are selected, which represents a survey rate of approximately 0.6%.

**Weighting procedure**

The weight is derived as the product of a design weight (which incorporates design information and non-response) and a factor that calibrates the sample to the independent demographic estimates (using *a posteriori* stratification method by NUTS-2, sex and 5-year age groups; NUTS-3 (or groups of NUTS-3) by six age groups; and NUTS-3 (or groups of NUTS-3) by sex).

**Data collection**

Interviews are carried out on a face-to-face basis with the help of portable computers (CAPI). All information is obtained by interview.

The field staff comprises 185 interviewers.

46% of the interviews of persons aged 15-74 years were carried out by authorised third parties.

The average response rate in 2005 was 87.4%. Refusals were 14% of the total non-response.

**ROMANIA (RO)**

**General**

The whole country is covered. Only private households are surveyed.

The target population includes all the Romanian citizens, resident in Romania. The survey covers all the members of the selected households including the persons absent from home for a long period (over 6 months), if they are preserving family relations with the household to which they belong, such as conscripts, pupils and
students away for study, persons absent due to work, prisoners and persons temporarily in hospitals for medical cure.

A household is defined as a group of two or more persons, usually living together, being generally relatives, managing the household in common, entirely or partly participating in income formation and spending. The person stating that he or she does not belong to any household, that he or she lives and manages the household all by him or herself is considered as a single person household.

**Sampling Plan**

The sampling plan is a two-stage probability sampling of clusters of housing units.

Because of the lack of appropriate registers (dwelling register, population register etc), the household surveys carried out by NSI-Romania are based on the repeated use of a master sample, which involves further the use of multi-stage sampling designs. LFS sampling design is founded on a two-stage sampling technique.

The primary sampling unit, corresponding to the selection of the master sample, is a group of census sections.

The secondary (ultimate) sampling unit, corresponding to the selection of the survey sample, has been the cluster of 3 dwelling units.

In the first stage, a stratified random sample of 780 areas, Primary Sampling Units (PSUs), was designed after the 2002 census, using as stratification criteria the residence area (urban/rural) and county (corresponding to NUTS-3 level) – 88 strata in all. This is the Multifunctional Sample of Territorial Areas, so called the master sample EMZOT. The EMZOT sample has 427 PSUs selected from urban area and 353 PSUs selected from rural area.

In the second stage, 9,360 clusters, composed of three housing units each, are systematically selected from the initial sample of PSUs. The final sample consists of 28,080 dwelling units each quarter. All households within each sampling unit are included.

The overall sampling rate, estimated as ratio between number of sampled dwellings, after the two sampling stages, and number of dwellings at country level, is about 0.38%.

Each sampling unit is observed for four quarters according to the rotation pattern 2-(2)-2.

**Weighting Procedure**

The weights are calculated in three steps. The first step assigns the inverse of the selection probabilities to each sampled dwelling unit. The second step adjusts for non-response, categorising the responding dwelling units by the following characteristics: county (NUTS-3) and urban/rural residency. The third and final steps consists of calibrating the secondary weights to the best latest available population
totals by region / urban-rural residency, gender, 14 age groups (0-14, 15-19, ..., 70-74, 75 and older) and the households totals by region, using the SAS macro Calmar.

In the calculation of weighting factors the totals known at population level from current demographic statistics, recalculated based on 2002 Census population, available twice a year (1st of January and 1st of July) are used. The current demographic statistics used to calibrate the LFS estimates also include the institutional population.

**Data Collection**

The data are collected only by face-to-face interviews using paper questionnaires. Data are collected with identical questionnaires through the whole year. The questionnaire is divided into two parts: dwelling questionnaire and individual questionnaire.

The data are collected by 780 field workers with face-to-face interviews using paper questionnaires.

The average response rate in 2005 was 96.0%. Refusals were 29% of the total non-response.

In 2005, 28% of the interviews of persons aged 15-74 years were by proxy.

**Further methodological information**

In the case of the self-employed and unpaid family workers in agriculture, the threshold for employment is set at 15 hours in the reference week instead of 1 hour.

**SLOVENIA (SI)**

**General**

The Slovenian Labour Force Survey started in 1993 as an annual survey, using four weeks in May as the reference period. Since the second quarter of 1997 the LFS has been conducted as a continuous survey, providing quarterly results.

The survey covers the whole country. Only individuals in private households are surveyed.

Participation in the survey is voluntary.

Members of the household temporary absent for a period exceeding 6 months (army, hospitals, prisons, student’s homes) and persons living in other countries were excluded from the survey. Foreign nationals are included, if they correspond to the criteria of household. For the household members up to 15 years only very few questions are collected.

A household is a single person or a group of persons, who live together and share expenses related to common living and eating.
Sampling Plan

The basis of sampling frame is the Central Population Register of the Republic of Slovenia.

The sampling method is stratified systematic random sampling of addresses. All members of the household at the selected address are included.

Each quarter app. 7 100 households are in the sample, corresponding to an overall sampling rate of 1.0%.

Strata are defined by NUTS-3 (12) and type of settlement, defined according to the settlement size and proportion of farmers (6). Stratum allocation is proportional to the population distribution, but adjusted by previous non-response rates by stratum.

Each household is interviewed five times according to the rotation pattern 3-(1)-2.

Weighting Procedure

The data is weighted for unequal probability of selection and for non-response and post-stratified according to the known population distribution: age (0-14, 15-19, 20-29, 30-39, 40-49, 50-59, 60-69, 70+), sex and region (NUTS-3 level). The post-stratification is done on a household level, with members of the same household thus receiving different weights, and benchmarked to population totals. Institutional population is included in population totals.

Data Collection

The data are collected by approximately 30 field workers with face-to-face interviews using electronic questionnaires and 10 telephone interviewers. All repeated interviews are carried out by telephone if the household has a telephone. Repeated interviews in the households without telephone are done face-to-face.

The average response rate in 2005 was 83.8%. Refusals were 60% of the total non-response.

Approximately 58% of the interviews are carried out by proxy

SLOVAKIA (SK)

General

The whole country is covered. Only private households are surveyed.

Participation in the survey is compulsory.

The target population of the survey is every person aged 15 and over, living in the household of the selected dwelling without regards to permanent, temporary or
unregistered stays. Data for the students living in hostels, schoolchildren living in boarding schools and persons living temporarily in worker homes are collected within the households to which they belong. Inmates of prison or mental institutions, foreign citizens with temporary stay and domestic servants are not surveyed. Since the first quarter of 1997 the conscripts on compulsory military service are included in the LFS.

A household is a group of persons sharing common accommodation and house keeping. Persons living on their own constitute one-person households.

**Sampling Plan**

The sampling design is a stratified two-stage probability sampling of dwelling units, using the Census of Population 2001 as the basis for the sampling.

The strata are formed by (79) districts, which correspond to the NUTS-4 level.

The primary sampling units (PSU) correspond to the Census Administrative Units. These are selected at the first sampling stage in each district with probability proportional to the district's population size. Each PSU can be selected more than once.

At the second stage, five dwelling units are selected from each instance of the PSU using a simple random sampling method.

The sample size is about 10 250 dwellings every quarter, representing 0.6% of all permanently occupied dwellings.

Every selected dwelling remains in the survey for five consecutive quarters.

**Weighting Procedure**

Data from the survey for all persons participating in the survey were weighted by administrative data on total population (including institutional population) as of 1 January 2004 (for the 1st and 2nd quarter) and as of 1 January 2005 (for the 3rd and 4th quarter) by region, sex and age groups.

Extrapolation to the population is done at the level of individuals. The average sample size was 24 477 persons (aged 15 and over). The population and the sample are the subject of a post-stratification by NUTS-3 administrative region (8 regions altogether), sex and five-year age groups. In each of the strata thus obtained the weight \( w_i \) is assigned to each person in the sample:

\[
w_i = \frac{N_i}{n_i}, \text{where}
\]

\( N_i \) - the number of persons in stratum \( i \) of population (age 15+)

\( n_i \) - the number of persons in stratum \( i \) of the sample (age 15+).
Data Collection

The data are collected by face-to-face interviews using paper questionnaires. In most cases the repeated interviews are carried out via telephone using paper questionnaires.

The field staff comprises 51 interviewers. The average response rate in 2005 was 93.1%. Refusals were 77% of the total non-response.

The average percentage of proxy interviews in 2005 for persons aged 15-74 years was 62%.

FINLAND (FI)

General

The Finnish Labour Force Survey (LFS) started in 1959. Finnish LFS data has been delivered to Eurostat since 1995. In late 1990's various kinds of methodological development was done, and changes introduced to the Finnish LFS due to EU harmonisation. Since 2000 the Finnish LFS is a strictly continuous survey.

The survey is a monthly survey with the reference weeks distributed uniformly throughout the month. The data for the first two months of the each quarter are estimated on the basis of 4 survey weeks and data for the third month on the basis of 5 survey weeks. The survey provides monthly, quarterly and annual results.

Participation in the survey is voluntary.

The whole country and the Autonomous Territory of the Åland Islands are covered, as well as both private and collective households.

The target population contains population aged 15 to 74 who are registered as permanently resident in Finland, including those who are temporarily abroad for a period of less than a year, members of the armed forces, and institutional population. The population also includes foreign nationals who have been living in Finland for at least a year or intend to do so.

As Eurostat needs information about the total population, an additional sample is selected of persons aged over 75 years. They are not interviewed but their register data are included in the response database on a quarterly basis for Eurostat purposes. The data for persons aged less than 15 years is included in the household sample. They, however, do not belong to the target population.

A household consists of persons who live, share meals or otherwise use their income together.

Sampling plan

The sampling design used in Finland is stratified systematic sampling of elements, having as a sampling frame the total population database maintained by Statistics Finland. It is based on the Population Information System of The Population Register
Centre and updated regularly. The population of individuals is divided into strata. The strata are formed according to NUTS-1 regions with over-sampling from the Autonomous Territory of the Åland Islands.

The sampling unit is the individual. The sample comprises 12 000 persons per month, or 36 000 persons per quarter corresponding to a survey rate of 0.9% over the quarter.

In each stratum systematic random selection is applied to the frame sorted according to the domicile code which yields implicit geographic stratification. So far no indication of selection bias due to systematic sampling has been encountered, so the selection procedure can be approximated by simple random sampling without replacement (SRSWOR).

The sample for the household-based study was based on the individuals who participated in the last wave of the current study design of the continuous Community LFS in 2005. Household members were interviewed throughout the year 2005. The reference person was interviewed as usually in the continuous survey. After that the composition of household was checked and persons aged 15 or more were interviewed.

Because the continuous survey sample frame only includes persons aged 15 to 74 years, a separate sample of dwelling units was drawn to correct the frame for elderly persons. A technical sample of persons aged 75 or more was added to the file of the fifth wave after data collection. This technical sample corrects the sampling frame, which in the continuous LFS is limited to persons aged 15 to 74 years. However, this technical part of the sample was not interviewed. Instead, data was imputed assuming that persons aged 75 or more are outside the labour force together with data available from administrative files.

Thus, in the LFS sample there are two sets of persons aged 75 or older for all four quarters of the year 2005. One part is coming from the household interviews and the second part from the technical sample of households (dwelling units), where all persons were aged 75 or more, added to the file after data collection. The data in this part was imputed to be outside the labour force and for them only the data available from administrative files were incorporated. The technical sample is needed, because the original LFS sample does not include households, where all persons are aged 75 years or more.

Respondents are questioned always in the same month of the quarter at quarterly intervals for 3 successive quarters and then, after skipping one quarter, for 2 further consecutive quarters. This corresponds to a quarterly rotation pattern of 3-(1)-2.

Until March 2005, retired persons aged 65-74 were interviewed only every second quarter, with responses for the times skipped supplied from the preceding interview. Starting from March this procedure was terminated and, thus, by the end of 2005, all retired persons aged 65-74 were treated normally.
Weighting procedure

A. Two phase weighting of individuals

**Phase 1 - Post-stratified weights:** The strata are now constructed by gender, age (6 categories: 15-24, 25-34, etc.) and region (21 categories consisting of the regions on NUTS-3 and the Greater Helsinki area), totalling 252 cells.

**Phase 2 - Calibrated weights:** Subsequently the post-stratified weights are calibrated according to gender, age group (5-year), region, reference week and register-based job-seeker status taken from an administrative register maintained by Ministry of Labour. The register indicator is further divided into three categories according to the length of being unemployed in the register: 0-180 days, 181-360 days and over 360 days. Additionally four indicators, which tell if the respondent is included in the unemployed job-seekers register but not actually unemployed at the time of measurement. These persons may, e.g., be in some type of education to improve their employability. For practical reasons the register counts were selected for the last day of each month for use with the next month's LFS data.

B. Weighting of the sub-sample of households

**Post-stratified weights:** The post-stratified weights were calculated separately for the household sample part and the technical sample of households (all persons in the household who were aged 75 or more).

a) Post-stratified weights for the household sample were adjusted corresponding to the population numbers of the survey quarter in the age groups 15-74 years by regional post-strata (21 categories consisting of the regions on NUTS level 3 and the Greater Helsinki area).

b) Post-stratified weights for the technical sample of households (all persons in the household who were aged 75 or more) were adjusted corresponding to the population numbers of the survey quarter in the age 75 or more by gender post-strata.

The combined post-stratified weights were composed from these two parts.

Data collection

The Labour Force Survey is a computer-aided telephone interview using decentralized computer assisted telephone interviewing (CATI). Interviews are carried out in Finnish, Swedish and English. Demographic information (sex, year of birth, marital status, nationality) and information about highest level of completed education or training, and field of education are obtained from administrative sources (population register, Register of Completed Education and Degrees).

The field staff comprises 140 interviewers.

6.9% of the interviews of persons 15-74 years old were carried out by authorised third parties.
The average response rate was 83.2% in 2005. Refusals were 65% of the total non-response.

**SWEDEN (SE)**

**General**

The Swedish Labour Force Survey started in 1959, with a quarterly survey starting in 1963 and a monthly survey in 1970. From 1999, the reference weeks are distributed uniformly throughout the year and the survey provides monthly, quarterly and annual results. In April 2005 a new questionnaire was introduced, together with a full renewal of the sample.

Participation in the survey is voluntary.

Through sampling of individuals persons living in both private and collective households are covered. Persons living in a collective household are also recorded in the central population register and are therefore sampled as well as persons living in private households.

The resident population for the purposes of the survey comprises persons between the ages of 15 and 74 who are domiciled in Sweden according to the population register.

A household is either a person that lives alone or persons that live together and share household expenses. Members of the household are included in wave 8 (the last wave) according to EU definitions of economic households.

**Sampling plan**

The sampling design is a single stage stratified single stage simple random sampling of individuals.

The sampling frame is Statistics Sweden’s Register of the Total Population which also contains auxiliary information on sex, age and region (county).

The sample is drawn at the end of the fourth quarter every year to cover the coming year’s need of new sample persons. When the sample is drawn it is stratified according to county, sex, and age group (15, 16-64, 65-74). In this way 144 strata are constructed. The inclusion probabilities are in general proportional to the size of the strata, although some small counties have to be overrepresented in the sample. The inclusion probabilities of the age groups 15 and 16-74 are also adjusted to meet the needs of Eurostat’s demands. The inclusion probability for individual \( k \) on a certain survey occasion is calculated approximately as:

\[
\pi_k = \frac{n_{h_j}}{N_{h_j}}, \text{ where}
\]
\( n_{h,j} \) = The number of individuals in the sample that belong to sample stratum \( h \) and to the year’s sample \( j \).

\( N_{h,j} \) = The number of individuals in the age group 16-64 in sample stratum \( h \) at sample selection occasion \( j \).

Every month about 20 000 persons are included in the sample.

The LFS sample consists of three separate samples, one for each month in the quarter. Every monthly sample consists of 8 rotation panels (waves), of which 7/8 recur after 3 months and 1/8 is replaced by new individuals. Persons in the sample are interviewed once a quarter with a total of eight interviews during a two-year period, after which they leave the sample. Due to the introduction of the new Swedish LFS as from April 2005 there was a break in the rotation as no persons sampled for the old LFS were allowed to continue being interviewed in the new LFS. This meant that a majority of the respondents in April were interviewed for the first time, although they were assigned to different rotation panels.

**Weighting procedure**

The estimates build on regression estimators (GREG) with a set of auxiliary information. The auxiliary variables are: sex*age (5 year age groups), region (NUTS 3), nationality at birth, information on employed persons by industry and persons who have enrolled at a job-centre as unemployed and are looking for work. The registers which are used to obtain the auxiliary variables are the Register of Total Population (RTB), The Employment Register (SREG) and National Labour Markets Board’s Register of job-seekers (SOK). The estimator is a generalised regression estimator (GREG) briefly described below:

From a given sample design we have a sample \( s \) with a sample size \( n_s \). A part \( r \) of size \( n_r \) are respondents. A GREG estimator for a total, based on data from this sample is:

\[
i_y = \sum \hat{y}_k w_k y_k
\]

where

\( \hat{y}_k \) = Estimate of a total, e.g. number of employed

\[
y_k = \begin{cases} 1 & \text{If the individual has the characteristic in question} \\ 0 & \text{Otherwise} \end{cases}
\]

\( w_k \) = Final weight

\( w_k = g_k \times d_k \)

\( d_k = 1/\left(\pi_k \hat{d}_k\right) \) = Design weight with respect to the non response.
\[ \pi_k = \text{Inclusion probability for individual } k \]

\[ \hat{\theta}_k = \text{The estimated probability of being a respondent for individual } k, \quad \hat{\theta}_k = \frac{m_h}{n_h} \]

when \( k \) belongs to stratum \( h \).

\[ g_k = 1 + \left( t_x - \hat{t}_x \right) \left( \sum_r \frac{x_k x'_k q_k}{\pi_k \hat{\theta}_k} \right)^{-1} x_k q_k \]

Correction factor by using the auxiliary information

\[ x_k = (x_{k1}, \ldots, x_{jk}, \ldots, x_{Jk}) \text{ is a vector for auxiliary information of length } J. \]

\( q_k \) is a known constant.

\[ t_x = (t_{x1}, \ldots, t_{xj}, \ldots, t_{xJ}) \text{ is a vector of length } J \text{ consisting of known register totals}. \]

\[ \hat{t}_x = (\hat{t}_{x1}, \ldots, \hat{t}_{xj}, \ldots, \hat{t}_{xJ}) \text{ is a vector of estimates of the elements in vector } t_x. \]

Where the estimate of a given element \( t_{xj} \) is given by:

\[ \hat{t}_x = \sum_r a_k x_k \]

The variance for \( \hat{t}_x \) is estimated as

\[ \hat{V}(\hat{t}_x) = \sum \sum_r \frac{\pi_{kl} \hat{\theta}_{kl} - \pi_{kl} \hat{\theta}_l \hat{\theta}_k}{\pi_k \hat{\theta}_k} w_k w_l e_k e_l \]

where

\( \pi_{kl} \) is the second order inclusion probability,

\( \hat{\theta}_{kl} \) is the estimated probability that \( k \) and \( l \) belongs to \( r \) (i.e. the respondents),

\[ \hat{\theta}_{kl} = \frac{m_h m_l - 1}{n_h n_l - 1}, \quad k \neq l \]

and

\[ e_k = y_k - \mathbf{B} \mathbf{x}_k, \quad \mathbf{B} = \left( \sum_r \frac{x_k x'_k q_k}{\pi_k \hat{\theta}_k} \right)^{-1} \sum_r \frac{x_k y_k q_k}{\pi_k \hat{\theta}_k} \]

**Data collection**

The information is, for the most part, collected in telephone interviews by Statistics Sweden's interviewers. Interviews are conducted using computer assisted telephone technology. Information on sex, age, region, country of birth, industrial code, level
and field of education and years of residence in Sweden are collected from administrative registers.

The field staff comprises about 200 interviewers.

In 2005, 2.8% of the interviews of persons 15-74 years old were proxy interviews.

The average response rate in 2005 was 82.2%. Refusal were approximately 43% of the total non-response.

**UNITED KINGDOM (UK)**

**General**

The survey started in 1973 as a biennial survey (not using the ILO definition of unemployment). It was redesigned in 1984 as an annual survey and from 1992 as a continuous, quarterly survey.

The survey covers private households and includes persons who are temporarily absent. Students living in university accommodation (e.g. halls of residence) are sampled via their parents living in private households. In Great Britain, an additional sample is drawn to cover persons living in National Health Service/Hospital Trust accommodation.

The UK LFS is a voluntary survey.

The resident population comprises persons who regard the sample address as their main address. Persons who have lived in a dwelling for more than six consecutive months are considered a member of the resident population, even if they do not regard this as their principal dwelling. Persons absent for more than six months are not regarded as a member of the resident population.

A private household comprises one or more persons whose main residence is the same dwelling and/or who share at least one meal per day. Students aged 16+ who live in a collective household but who return to their parents for the holidays are also regarded as being a member of their parents’ household.

The year is divided into quarters of 13 weeks: winter (December to February), spring (March to May useful for results at EU level), summer (June to August) and autumn (September to November). For each of these periods, the reference weeks are distributed uniformly over the 13 weeks.

Labour market information is gathered for all persons who have reached 16 years of age.

**Sampling plan**

The sampling design is a stratified single stage systematic (single random in NI) probability sampling.
The survey unit is the postal address (the telephone number in the far north of Scotland). For most of Great Britain, the survey base is the Royal Mail's PAF (Postcode Address File), a database of all addresses receiving mail. The list is limited to addresses receiving fewer than 50 items of post per day, in order to exclude businesses. Because of the very low population density in the far north of Scotland (north of the Caledonian Canal), interviews are carried out exclusively by telephone with telephone directories being used as sampling frames. In Northern Ireland, the Rating and Valuation Lists (which serves for the administration of land taxes) is used.

Most of Great Britain constitutes one stratum, while the far north of Scotland forms a separate stratum and Northern Ireland three strata: Belfast and eastern and western Northern Ireland.

In Great Britain, a systematic sample is drawn each quarter from the three sampling bases, using a sampling interval of 1440 units. This yields 16 600 PAF addresses, 75 telephone numbers for the north of Scotland and 25 units of National Health Service housing. As the PAF is broken down geographically, the systematic sampling produces a pseudo-stratification effect which ensures that the sample is representative at regional level. In Northern Ireland, a simple random sample is drawn each quarter from each of the three strata, giving 650 addresses in all.

The sample design currently consists of about 55 000 responding households in Great Britain every quarter, representing about 0.1% of the GB population. A sample of approximately 2 000 responding households in Northern Ireland is added to this, representing 0.1% of the NI population, allowing United Kingdom analyses to be made.

A rotation system comprising five waves is used. Respondents are questioned 5 times at 13-week intervals and one-fifth of the sample is replaced each quarter.

Weighting procedure

The adjustment procedure is based on a three-stage a posteriori stratification. In each case, estimates are based on independent demographic estimates.

(a) The stratification variable for the first stage is the Local Authority District or Unitary Authority. This stage makes it possible to make adjustments for different rates of non-response in the various local authority areas and ensures that the results are geographically representative.

(b) The second-stage variables are sex and age group (0-15, each year of age in the 16-24 group and 25 +). This stratification is intended to ensure that the age profile of the 16-24 year olds is correct at national level.

(c) The variables in the third stage are region, sex and 5-year age group.

The three stages are applied by means of an iterative procedure designed to ensure that the estimates are consistent with the stratification variable sets.
**Data collection**

Interviews are carried out on a face-to-face basis with the help of portable computers (CAPI) for the interviews in the first wave. In the far north of Scotland (north of the Caledonian Canal) and for interviews in the second to fifth waves wherever possible, interviews are carried out by telephone (CATI). All information is obtained by interview.

Results for respondents who are not contacted in waves 2 to 5 or who refuse for circumstantial reasons are carried forward from the previous wave if an interview has been carried out in the previous wave.

The field staff comprises 650 telephone and face-to-face interviewers.

34% of the interviews of persons aged 16-74 years in 2005 were carried out by authorised third parties.

The average response rate in 2005 was 65.9%. Refusals were 89% of the total non-response.

**CROATIA (HR)**

**General**

The Labour Force Survey in Croatia was carried out for the first time in November 1996 and in June 1997. Since 1998 the survey is carried out every month when a part of the total sampled households is interviewed. Data are processed and published for each half-year period.

Only private households are surveyed and participation is voluntary.

The reference week for the LFS is the last week of the each month which does not contain public holidays.

The Labour Force Survey covers the whole country since 2000. (Before 2000 the sample frame used was the one based on data from Census 1991 and in this period the parts of Croatian territory with still ongoing war operations at the time when survey was prepared, could not be included in the sample frame.

The target population comprises all persons who usually reside in Croatia or intend to stay in Croatia for at least 12 months.

Household is a small economic group of persons that is usually, although not always, the group of relatives living together and sharing costs of living (housing, food, etc.).

**Sampling Plan**

The sampling design is a two stage stratified sample. First stage sampling frame is a list of area units called segments. Segments are created from one or more neighbouring 2001 Population Census areas and they do not cross borders of municipalities. Second stage sampling frame is a list of 2001 Population Census
dwellings within selected segments. Dwellings on sampling frame are dwelling in which one or more private households have been found in Population Census 2001. All members of all private households in dwellings are interviewed.

Segments are selected by PPS systematic sampling, where measure of size of segment is number of private households in segment according to Population Census 2001. They are used for whole year 2005. Within selected segments, dwellings are selected by simple random sampling. Different samples of dwellings are selected for two half years. After selecting a sample of segments, six non-overlapping sub-samples of segments are selected from sample of segments by systematic sampling. They are allocated to six months in each half year.

The sample is divided into 21 strata using proportional allocation. The strata are 20 counties and City of Zagreb area.

In the year 2005, 720 segments are selected. From each selected segment, 12 dwellings are selected for the first half of the year, and 12 dwellings are selected for the second half of the year. In total, 8 604 dwellings are selected for first half of the year, and 8 640 dwellings are selected for second half of the year, yielding an overall sampling rate of 0.6% for each half year.

No sample unit is carried over from previous years.

**Weighting Procedure**

The weights are calculated in several steps.

First design weights are calculated as the inverse of overall sampling probabilities. Sampling probabilities for persons are sampling probabilities for segments times sampling probabilities for dwellings times 1 (all households are selected) times 1 (all persons are interviewed). (Obviously, design weights for dwellings, households and persons are the same.)

Secondly, the non-response weights are calculated using weighting classes method. There are 57 weighting classes. In Croatia, municipalities are officially divided in two groups, according to the level of urbanisation. Weighting classes are 17 city quarters in City of Zagreb, and, in each of 20 counties, two groups of two types of municipalities. (There is no other information on the sampling frame that can be used for adjustment for non-response.) Non-response weights are inverses of weighted response rates (response rates are weighted by design weights).

Overall weights are design weight times non-response weights. In each weighting stage and in each stratum, weights are scaled to the number of persons aged 15 or more in the sample, which is population of interest. This ensures that for each strata mean weight is 1 and that non-weighted and weighted numbers of persons aged 15 or more are the same.

At the end, two sets of weights are calculated, multiplying weights by two different factors. One set of weights, i.e. persons’ weights, ensures that estimates of total numbers of persons are the same as numbers of persons in private households obtained from Department for population statistics. The other set of weight, i.e.
households' weights, ensures that estimated numbers of households are the same as numbers of households obtained from Department for population statistics. The second set of weights is only used for the estimation of certain national variables.

**Data Collection**

Data are collected by face-to-face interviews, using paper questionnaires.

The number of field-workers was 110 interviewers per month.

In 2005 the average response rate was 84.0%. Refusals were 38% of the total non-response.

In 2005, 38% of the interviews of persons aged 15-74 years were by proxy.

**Further methodological information**

The Croatian questionnaire does not differentiate persons who have found a job to start working in “at most” and “more than” 3 months (codes 11 and 12). These are all coded as 11.

**TURKEY (TR)**

**General**

Labour Force Surveys in Turkey started in 1966, while regular annual Labour Force Surveys applying ILO recommendations started in October 1988. The Turkish LFS was carried out in April and October each year from 1989 to 1999 with major changes in design introduced in October 1994. In 2004 the questionnaire was revised to conform to the Eurostat regulation. From 2000 onwards the survey has produced quarterly results, and from 2005 monthly results using moving 3 months averages.

The survey covers the whole country. Only private households are surveyed.

The population surveyed comprises all persons in the country excluding residents of collective households. Villages with fewer than 100 inhabitants are not in the sampling frame. Participation in the survey is compulsory.

A household is one persons or group of persons with or without a family relationship who live in the same house or in the same part of the house, who share their meals, earnings and expenditures and who take part in the management of the household and who render services to the household.

**Sampling Plan**

The Turkish LFS sample is based on a five-year master sampling plan starting in 2004. The sampling frame is based on the 2000 Dwelling Enumeration Study. The quarterly sample size is approximately 38 000 households.
The sampling design is a two stage stratified probability clustered sample of addresses.

In the first stage of sampling the primary sampling units are defined in urban areas and larger villages as blocks of addresses containing approximately 100 households. These are selected with equal probability using systematic sampling. Medium sized villages are sampled with probability proportional to size.

The final sampling units are addresses. In urban PSUs these are selected with equal probability using systematic sampling. In medium sized villages the households are selected with probability inversely proportional to size. The number of units selected from each PSU is determined so as to achieve a uniform overall sampling rate. All households within an address are taken into the sample.

Villages too small to permit sub-sampling of households are selected directly with equal probability using systematic sampling and all households with them taken into the sample.

Each household participates in the survey according to the rotation pattern 2-(2)-2.

**Weighting Procedure**

The results are weighted to the projections of the General Population Census 2000, using a three-stage procedure.

In the first stage each sampling units is assigned the design weights, which then are normalized to give an average weight of 1.0 per unit. In the second stage the initial weights are adjusted for non-response. These weights are also normalized.

In the final stage the weights are calibrated to the projected population distributions, using a three-step raking ratio method. The second step the rural-urban by age group distributions and the final step the sex by age group distributions. The calibration is iterated until any relative changes in the weights are within a pre-specified range. The final weights are then inflated by an overall inflation factor, i.e., the projected population divided by the sample size.

**Data Collection**

The data are collected each month by approximately 170 interviewers using Computer Assisted Personal Interviewing (CAPI).

Since the year 2004, the first week of each month starting with Monday and ending with Sunday has been used as the reference period and the field application is completed within approximately 15 days.

Overall response rate in 2005 was 85.1%.
ICELAND (IS)

General
The survey started in 1991 as a semi-annual survey. Since 2003 the survey has covered all weeks of the year uniformly, providing quarterly results.

The survey covers persons aged 16-74 years old in private households and collective households.

The resident population comprises persons registered with domicile in Iceland, excluding persons attached to foreign missions and registered persons living abroad for more than 6 months, but including Icelandic personnel in missions abroad.

The definition of private household used is the one of housekeeping unit.

Sampling plan
The sampling plan is a one-stage simple random sample without stratification.

Each quarter one fifth of the sample is renewed by a single random sample without replacement of persons younger than 75 in the first week of the quarter and older than 16 in the last week at the end of the rotation cycle.

The quarterly sample is sorted according to sex, age and residence and then allocated systematically (with random start) to the 13 weeks of the quarters so that each week is representative of the total sample by age, sex and residence. Persons younger than 16 on the last day of the reference week, are not included in the weekly sample until this age is reached.

The survey frame is the National Population Register; all persons aged 16-74 years of age with domicile in Iceland.

The sample size each quarter is 4 030 individuals, giving an average survey rate of 1.9%.

The survey unit is the individual.

The household sub-sample is selected from the fifth and last wave so that the sampling probability is inversely proportional to the number of persons aged 16-74 years in the household of the drawn individual.

The survey follows a rotating panel sample design, according to the rotation design 3-(2)-2.

Weighting procedure
The a posteriori stratification variables are 5-year age groups and sex.

The weighting factors are calculated as follows:

\[ w = \frac{N(sa)}{n(sa) + n'(sa)} \]
where $N$ = population, $s$ = sex, $a$ = age, $n$ = sample size and $n'$ = estimated over-coverage (i.e. registered persons living abroad for more than 6 months as detected in the field work)

**Data collection**

Interviews are carried out by telephone with the aid of computers (CATI). Information on sex, age, years of residence, citizenship and marital status are obtained from administrative sources (National Population Register).

The field staff comprises on the average 10 interviewers per quarter.

In 2005, less than 1% of the interviews were carried out by authorised third parties.

The average response rate in 2005 was 82.1%. Refusals were 52% of the total non-response.

**NORWAY (NO)**

**General**

The Norwegian labour force survey started in 1972 as a quarterly survey. From 1996, the survey has been designed as a continuous survey providing quarterly results.

It covers collective households.

Participation in the survey is compulsory.

The definition of household used is concept of housekeeping unit, but only to cover the structure of the household (household members who don’t belong to the family unit are not asked any questions about their labour market participation).

The definition of resident population is the *de jure* one based on the Central Population Register.

**Sampling plan**

Inhabitants in all municipalities are randomly selected, on the basis of a register of family units. Each family member aged 16-74 participates in the survey, answering questions about their situation during a specified reference week.

The sampling frame is based on the Central Population Register, which is continuously updated by the local population registration offices. The sampling frame is stratified according to county (NUTS-3 regions).

Each quarter the sample consists of 24 000 persons (12 000 families), corresponding to 0.8% sampling rate.

Each family participates in the survey 8 times at 3-monthly intervals during a period of 8 quarters.
**Weighting procedure**

The initial weights are adjusted by post-stratification according to sex, age groups (16-19, 20-24, ..., 70-74) and employment status, altogether 96 ($=2^2*12*4$) post-strata. The variables used for post-stratification are based on information from the Central Population Register, the Register of Employees and the Tax Register. Finally, the post-stratification adjusted weights are calibrated within each of the 19 counties, which is equivalent to the NUTS-3 level, with respect to the marginal totals of the same auxiliary variables. The expansion factors are calculated according to the population totals aged 16-74, i.e. the institutional population included.

**Data collection**

Interviews are carried out by telephone (CATI). Information on age, sex, county of residence, children below 16 years, nationality and years of residence are obtained from administrative sources (population register).

The field staff comprises round 150 interviewers per quarter.

In 2005 14% of the interviews were carried out by authorised third parties.

Response rate was approximately 88% in 2005.

**SWITZERLAND (CH)**

**General**

The survey is conducted in the second quarter of each year (April-June), having the reference week the week before the interview.

The survey population consists of all persons living in private households aged 15 years and older. The SFLS covers only the permanent resident population in Switzerland and excludes some categories of foreign persons. The permanent resident population includes all persons who officially reside in Switzerland for the entire year. Swiss citizens, foreign citizens holding a permanent residence permit or a residence permit valid for at least one year, international civil servants, diplomats and their family members all fall into this category.

Only private households are covered.

The participation in the survey is voluntary.

A household comprises either a person living alone or two or more persons, whether or not they are of the same family, who usually occupy the same dwelling (dwelling concept).

**Sampling plan**

Since 2003 the Swiss LFS is divided in two parts:
a) Standard sample (36,000 households/persons). The base used for the standard sample are the registered phone numbers which covers until now more than 90% of the Swiss population.

b) Extra sample of foreign persons (15,400 persons). The base used for the extra sample is the register of foreign persons in Switzerland. The register allows stratifying the sample according individual characteristics (region, nationality).

The standard sample is stratified by region and the number of persons (population) by region; the extra sample of foreign persons is stratified by region, nationality-groups and the number of persons in this categories.

The sampling unit is the phone number for the standard sample (but only one person is interviewed per household); in the extra sample the sampling unit is the individual (as it is selected from the register of foreign persons).

The sampling plan is in two stages. Stratification is carried out by administrative (Swiss cantons) regions in a first level and by number of persons (population) living in administrative regions in a second level.

The sampling rate for the total sample: 0.8% of all persons aged 15 years and older.

In the SLFS a rotation system comprising five waves is used. Each unit (person) remains in the sample for five consecutive years. The size of the first wave is normally 27-29% of the total sample size.

Weighting procedure

The weighting procedure is based out on a two-phase process: At first the base weights are obtained as the reciprocal of the inclusion probability of the sample units. Then the sample is stratified \textit{a posteriori} by region (NUTS-2), marital status, 5-years age-groups, sex, nationality-groups (North-EU, South-EU, West-Balkan, Other). This procedure is applied iteratively. The expansion factor is a factor to total population (15 years and older).

Data collection

Interviews are carried out by telephone (CATI). In the CATI questionnaire, data previously gathered in the preceding wave are included. The questionnaire exists in 6 languages (German, French, Italian, Serbo-Croatian, Albanian, English, Turkish and Portuguese). All information is obtained by interview.

The field staff comprises around 400 persons.

0.8% of the interviews in the standard sample were carried out by authorised third parties, but 0.4% of the extra sample.

The response rate in 2005 was 82.0%. Refusals were 33% of the total non-response.
